## Parallel programming in Chapel

ALEX RAZOUMOV alex.razoumov@westgrid.ca

JUAN ZUNIGA

### Why another language? https://chapel-lang.org

- High-level parallel programming language
  - ► "Python for parallel programming"
  - much easier to use and learn than MPI; few lines of Chapel typically replace tens of lines of MPI code
  - ▶ abstractions for data distribution/parallelism, task parallelism
  - optimization for data-driven placement of subcomputations
  - ▶ granular ("multi-resolution") design: can bring closer to machine level if needed
  - everything you can do in MPI (and OpenMP!), you should be able to do in Chapel
- Shared- and distributed-memory parallelism built in
- Focus on performance
  - compiled language; simple Chapel codes perform as well as optimized C/C++/Fortran code
  - ► reportedly, very complex Chapel codes run at ~70% performance of a similar well-tuned MPI code (not bad, but room to improve)
- Perfect language for learning parallel programming for beginners
- Open-source: can compile on any Unix-like platform
  - ▶ precompiled for MacOS (single-locale via Homebrew)
  - ► Docker image http://dockr.ly/2vJbi06 (simulates a multi-locale environment)

- Cedar (OmniPath) / Graham (InfiniBand) / Béluga (InfiniBand)
  - ► https://docs.computecanada.ca/wiki/Chapel

```
$ source /home/razoumov/startSingleLocale.sh
$ chpl --version
$ source /home/razoumov/startMultiLocale.sh
$ chpl --version
```

- Fairly small community at the moment:
   too few people know/use Chapel ← relatively few libraries
- You can use functions/libraries written in other languages, e.g. in C
  - (1) direct calls will always be serial
  - (2) high-level Chapel parallel libraries can use C/F90/etc libraries underneath

### Our workshop

# PART 1: BASIC LANGUAGE FEATURES

- running single-locale Chapel codes on Cedar
  - interactive jobs vs. batch jobs
- quicky on running Chapel on your laptop
- problem description: heat transfer equation
- variables
- ranges and arrays
- conditionals
- for loops
- config variables
- timing code execution

See lesson notes

# PART 2: TASK PARALLELISM

- parallel concepts
  - concurrency vs. true parallelism
  - concurrency vs. task locality
- fire-and-forget tasks
  - ▶ begin statement
  - ► cobegin statement
  - ► coforall loops
  - ► forall loops
- task synchronization
  - ► sync statement
  - sync variables
  - ► atomic variables
- task-parallelizing the heat transfer solver (if we have time)

See lesson notes

## PART 3: DOMAIN PARALLELISM

- running multi-locale Chapel codes on Cedar
- simple multi-locale codes
- domains and single-locale data parallelism
- distributed domains
- heat transfer solver on distributed domains
- periodic boundary conditions
- writing to files

See lesson notes

### Numerical problem: 2D heat transfer equation

- Imagine a metallic plate initially at 25 degrees
- Simple 2D heat (diffusion) equation

$$\frac{\partial T(x,y,t)}{\partial t} = \frac{\partial^2 T}{\partial x^2} + \frac{\partial^2 T}{\partial y^2}$$

- Discretize the solution  $T(x, y, t) \approx T_{i,i}^{(n)}$  with i = 1, ..., rows and j = 1, ..., cols
  - ▶ upper left corner is (1,1), lower right corner is (rows, cols)
- Initial condition:  $T_{i,j}^{(0)} = 25$
- Boundary condition: upper side  $T_{0,1..\text{cols}}^{(n)} \equiv 0$ , left side  $T_{1..\text{rows},0}^{(n)} \equiv 0$ , bottom side  $T_{\text{rows}+1,1..\text{cols}}^{(n)} = 80 \cdot j/\text{cols}$ , right side  $T_{1..\text{rows},\text{cols}+1}^{(n)} = 80 \cdot i/\text{rows}$  (linearly increasing from 0 to 80 degrees)
- Discretize the equation with forward Euler time stepping

$$\frac{T_{i,j}^{(n+1)} - T_{i,j}^{(n)}}{\Delta t} = \frac{T_{i+1,j}^{(n)} - 2T_{i,j}^{(n)} + T_{i-1,j}^{(n)}}{(\Delta x)^2} + \frac{T_{i,j+1}^{(n)} - 2T_{i,j}^{(n)} + T_{i,j-1}^{(n)}}{(\Delta y)^2}$$

## Numerical problem: 2D heat transfer equation (cont.)

- For simplicity assume  $\Delta x = \Delta y = 1$
- Use  $\Delta t = 1/4$
- The finite difference equation becomes

$$T_{i,j}^{(n+1)} = \frac{1}{4} \left[ T_{i+1,j}^{(n)} + T_{i-1,j}^{(n)} + T_{i,j+1}^{(n)} + T_{i,j-1}^{(n)} \right]$$

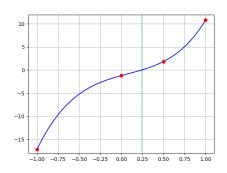

- The objective is to find  $T_{i,j}$  after a certain number of iterations, or when the system is in steady state
- Can increase the number of points in the grid to illustrate the advantage of parallelism

### Serial exercise: using *procedures* and control flow

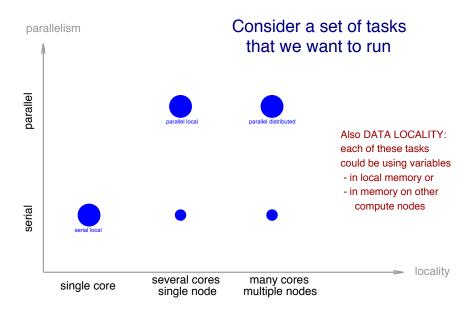

Look up Chapel procedures

Write a Chapel code to find the root of the equation  $x^5 + 8x^3 - 2x^2 + 5x - 1.2 = 0$  using the bisection method in the interval [-1,1]

- Calculate the function at the ends and the midpoint of the interval
- Depending on the signs of the three computed values, let the midpoint be either the new left or the new right end
- Repeat until your error is below  $\Delta x = 10^{-8}$

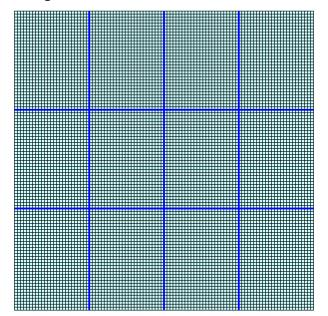

#### Parallelism vs. TASK LOCALITY

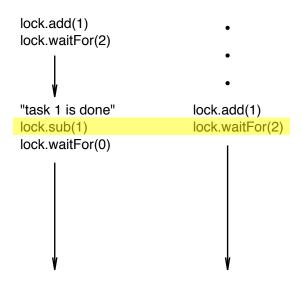

### Task- vs. data-parallel

	single locale shared memory parallelism	multiple locales distributed memory parallelism + likely shared memory parallelism
task parallel	config var numtasks = 2; coforall taskid in 1numtasks do writeln("this is task ", taskid);	forall loc in Locales do on loc do writeIn("this locale is named ", here.name);
data parallel	var A, B, C: [11000] real; forall (a,b,c) in zip(A,B,C) do c = a + b;	use BlockDist; const mesh = {1100,1100} dmapped Block(boundingBox={1100,1100}); var T: [mesh] real; forall (i,j) in T.domain do $T[i,j] = i + j;$

### Array decomposition

### Race condition

Note: lock.waitFor() is not a collective operation

### Data-parallel exercise: compute $\pi$ with forall loop

Write a parallel Chapel code to compute  $\pi$  by calculating the integral numerically through summation

$$\pi = \int_0^1 \frac{4 \, dx}{1 + x^2}$$

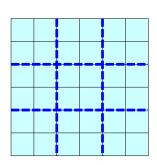

### Parallelism cheatsheet

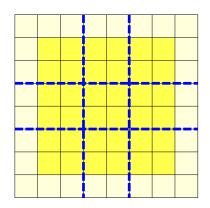

- for is a serial loop; a..#n means n iterations, a..b means b-a+1 iterations
- forall loop is executed cooperatively by all local cores in parallel, or by remote locales
  that own the corresponding indices/elements (subdividing their local iterations among
  their local cores); number of threads scales to the number of available cores
- coforall loop creates a new task per each iteration (cycling through locales or tasks inside a locale)
- begin { ... } spins statements inside off into a new task
- sync { ... } pauses until the children have synced back up
- $\begin{table line 2 line 3 } runs each line in a new task; can be grouped with () \\$
- Built-in variables and arrays
  - ► numLocales is the number of locales
  - ► Locales stores an array of compute nodes on which the program is executing
  - ▶ locale.id is the ID of the current locale
  - ▶ locale.maxTaskPar is the runtime maximum number of tasks on the current local
  - ▶ locale.numCores is the locale's number of compute cores
  - ▶ locale.name is a locale's name
    - ▶ here evaluates to the locale on which the current task is running

#### Distributions

- BlockDist partitions indices into blocks according to a boundingBox domain and maps each block onto a separate locale
- ► CyclicDist maps indices to locales in a round-robin pattern starting at a given index
- ► BlockCycDist, DimensionalDist2D, PrivateDist, ReplicatedDist, StencilDist, BlockCycDim, BlockDim, ReplicatedDim

### Distributed domains

### Unstructured data

In addition to rectangular domains and arrays, Chapel supports less structured (and more dynamic) data

- Sparse domains and arrays: can be mapped to locales
- Associative domains and arrays: can be mapped to locales as of v1.19
  - associated domains are similar to Python's sets (unordered, unique indices)
  - associated domains with arrays on top are similar to Python's dictionaries
  - HashedDist supports custom index mapping to locales
- Opaque domains and arrays: distribution across locales currently not implemented
